Carrington Rotation 2163 commenced on March 4, 2015 at 24.2072 UT and ended with the beginning of CR2164, on May 5, 2015 at 21.438 UT.

This rotation began with six active sunspot regions of which the two largest, AR2325 and AR2331, were relatively small and of about equal size (approximately 150-160 millionths), while the total sunspot area for the Sun stayed under 600 millionths for several days. Seven days into the cycle, activity dropped considerably, as these two active regions rotated to the far side of the Sun.

Two new areas, AR2334 and AR2335 appeared but occupied an area of only 20 and 10 millionths respectively, with a total of six spots, for a Wolf number of 36.

With CR2164 starting on May 5, a new sunspot area turned towards the Earth-side of the Sun, AR2339, which produced an X2.7-class flare and three M-Class flares. Four regions with a total of 49 spots gave a Wolf Number of 89. Within two days, AR2339 occupied 500, and within four days 900 millionths, and the activity really increased.

This became the dominant active region for 14 days, until it rotated to the far side. Total flare activity for the period between May 5 and May 14 was one X-class, four M-class and 70 C-class flares. Interestingly during this period, no B-class flares were recorded. A more detailed report on CR2164 will be published in an upcoming ALPO Journal.

How Are Sunspot Measured

Astronomers measure the sizes of sunspots as fractions of the Sun's visible area. Their favorite units are "millionth's." A sunspot that registers 1 millionth has a surface area equal to 0.000001 times the area of the Sun's Earth-facing hemisphere. Typically, a big sunspot measures 300 to 500 millionths. The entire surface area of the Earth is only 169 millionths of the solar disk. Source: <http://www.space-weather.com/sunspots/history.html>

What Are Wolf Numbers?

A "Wolf number" is a quantity that measures the number of sunspots and groups of sunspots present on the surface of the sun. The combination of sunspots and their grouping is used because it compensates for variations in observing small sunspots. It was named for the Swiss astronomer Johann Rudolf Wolf (7 July 1816 – 6 December 1893) who, in 1848, devised a way of quantifying sunspot activity. The Wolf number is 10 times the number of spot groups added to the total number of individual spots. Source: https://en.wikipedia.org/wiki/Rudolf_Wolf
